- Leakage when you wait too long.
- Low sexual desire.
- Difficulty being aroused.
- Trouble reaching orgasm.
- Painful sex.
- Vaginal dryness.
- Lichen Sclerosus.

What Is The O-Shot

A 30-minute office based procedure that involves injecting platelet rich plasma into the vaginal-clitoral area.

What Does The O-Shot do?

Growth factors concentrated by a centrifuge in the plasma portion of the blood stimulate stem cells to develop into new tissue in the form of collagen, blood vessels and fat cells. Patients will possibly benefit as follows: greater arousal from clitoral stimulation, younger, smoother skin of the outer vagina, tighter vaginal opening, stronger, more frequent orgasm, increased libido, increased lubrication, decreased pain for those experiencing pain with intercourse, and decreased urinary incontinence. The O-Shot is also used to treat a condition called lichen sclerosus.

What Can I Expect During The Procedure?

A few tablespoons of blood are drawn from your arm after numbing cream has been applied; the blood is then placed in a centrifuge and processed for twenty minutes under sterile conditions. Following this the blood is drawn into a syringe and injected into the area around the vaginal opening and clitoris that has been pre-prepared with numbing cream.

What Can I Expect After The Procedure?

You may resume normal activity, including sexual activity, following the procedure. Around 10% of patients will have excess arousal that will last up to one week. Other side effects include a mild pressure like sensation in the vaginal area. Patients may need a repeat procedure 8 - 10 weeks following the first injection. Studies have shown that some patients will receive benefit up to 2 -3 years for one injection. Overall 90% of the patients respond to their first injection.
